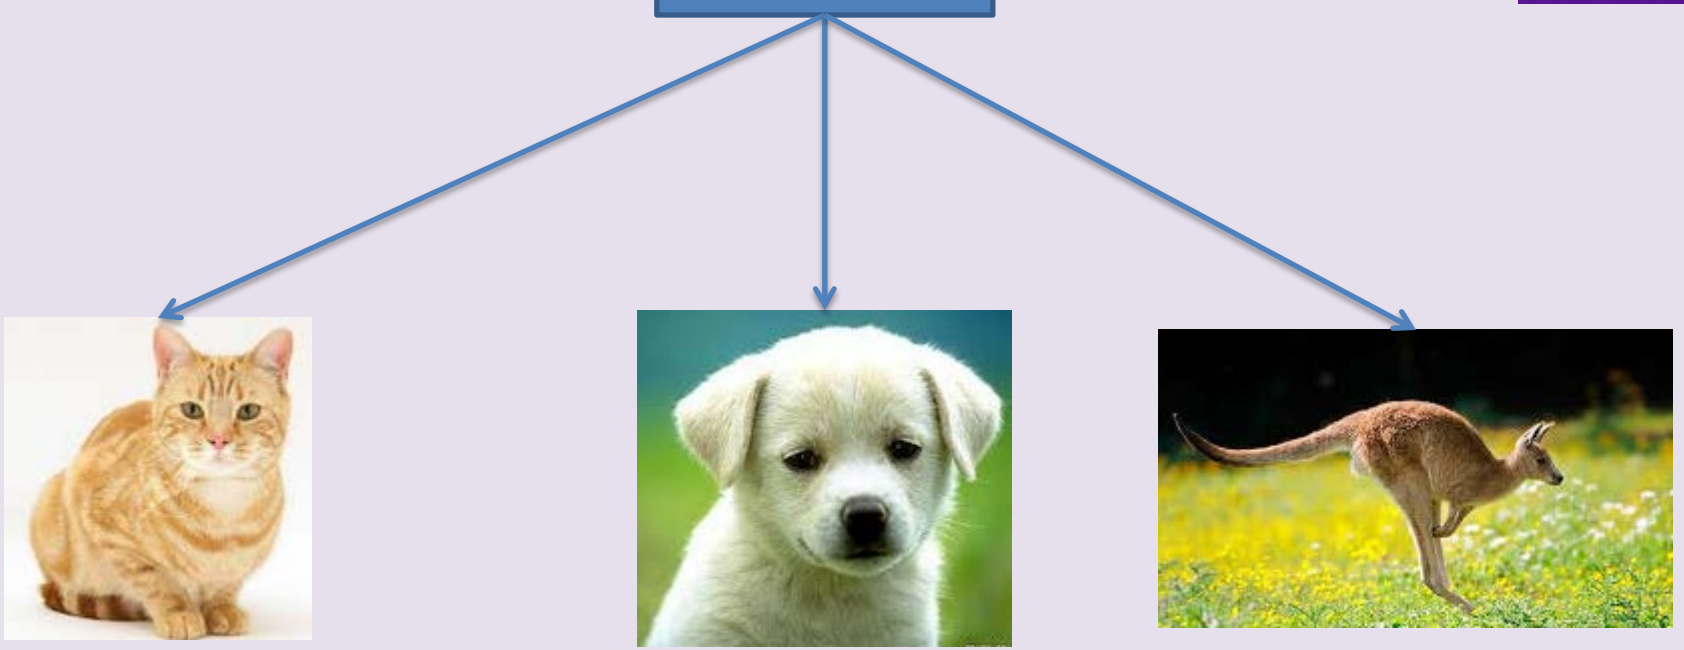
C++ Inheritance

NEW YORK UNIVERSITY
ABU DHABI

Classes in C++ can be extended, creating new classes which retain characteristics of the base class. This process, known as inheritance, involves a base class and a derived class: The derived class inherits the members of the base class, on top of which it can adds its own members.

Class Animal



C++ Inheritance

NEW YORK UNIVERSITY
ABU DHABI

```
class derived_class_name: public base_class_name
{

 /*...*/

 };

class Cat: public Animal
{
/*...*/
}
```

Example

```
// derived classes
#include <iostream>
using namespace std;

class Polygon {
  protected:
    int width, height;
  public:
    void set_values (int a, int b)
      { width=a; height=b;}
 };

class Rectangle: public Polygon {
  public:
    int area ()
      { return width * height; }
 };

class Triangle: public Polygon {
  public:
    int area ()
      { return width * height / 2; }
  };

int main () {
  Rectangle rect;
  Triangle trgl;
  rect.set_values (1,5);
  trgl.set_values (2,5);
  cout << rect.area() << '\n';
  cout << trgl.area() << '\n';
  return 0;
}
```

What is inherited from the base class?

NEW YORK UNIVERSITY
ABU DHABI

- Its constructors and its destructor
- Its assignment operator members (operator=)

What is inherited from the base class?

```
#include <iostream>
using namespace std;

class Base{
  public:
    Base ()
      { cout << "Base one called\n"; }
    Base (int a)
      { cout << "Base two called\n"; }
    ~Base()
    {
        cout<< "Base Destructor Called"<<endl;
    }
};

class Child1 : public Base{
  public:
    Child1 (int a)
      { cout << "Child one called\n"; }

     ~Child1()
    {
        cout<< "Child1 Destructor Called"<<endl;
    }
};

class Child2 : public Base{
  public:
    Child2 (int a) : Base (a)
      { cout << "Child two called\n"; }

    ~Child2()
    {
        cout<< "Child1 Destructor Called"<<endl;
    }
};

int main () {
  Child1 lily(0);
  Child2 lucy(0);
  return 0;
}
```

```
Base one called
Child one called
Base two called
Child two called
Child1 Destructor Called
Base Destructor Called
Child1 Destructor Called
Base Destructor Called
```

Pointers to base class

NEW YORK UNIVERSITY
ABU DHABI

A pointer to a derived class is type-compatible with a pointer to its base class.

```
#include <iostream>
using namespace std;
class Polygon {
   protected:
      int width, height;
   public:
      void set_values (int a, int b)
        { width=a; height=b; }
};
class Rectangle: public Polygon {
   public:
      int area()
        { return width*height; }
};
class Triangle: public Polygon {
   public:
      int area()
        { return width*height/2; }
};
int main () {
   Rectangle rect;
   Triangle trgl;
   Polygon * ppoly1 = &rect;
   Polygon * ppoly2 = &trgl;
   ppoly1->set_values (4,5);
   ppoly2->set_values (4,5);
   cout << rect.area() << '\n';
   cout << trgl.area() << '\n';
   return 0;
}
```

Pointer to Derived Class

What is the problem here?

C++ Polymorphism

NEW YORK UNIVERSITY
ABU DHABI

- C++ Inheritance
- C++ Polymorphism

C++ Polymorphism

NEW YORK UNIVERSITY
ABU DHABI

Polymorphism means that some code or operations or objects behave differently in different contexts.

Normally, when the term polymorphism in C++, refers to using virtual methods

Virtual member

NEW YORK UNIVERSITY
ABU DHABI

A virtual member is a member function that can be redefined in a derived class, while preserving its calling properties through references.

Virtual member

NEW YORK UNIVERSITY ABU DHABI

```
// virtual members
#include <iostream>
using namespace std;

class Polygon {
  protected:
    int width, height;
  public:
    void set_values (int a, int b)
      { width=a; height=b; }
    virtual int area ()
      { return 0; }
};

class Rectangle: public Polygon {
  public:
    int area ()
      { return width * height; }
};

class Triangle: public Polygon {
  public:
    int area ()
      { return (width * height / 2); }
};
```

```
int main () {
  Rectangle rect;
  Triangle trgl;
  Polygon poly;
  Polygon * ppoly1 = &rect;
  Polygon * ppoly2 = &trgl;
  Polygon * ppoly3 = &poly;
  ppoly1->set_values (4,5);
  ppoly2->set_values (4,5);
  ppoly3->set_values (4,5);
  cout << ppoly1->area() << '\n';
  cout << ppoly2->area() << '\n';
  cout << ppoly3->area() << '\n';
  return 0;
}
```
